Project Overview

Develop a Python-based console application that simulates a basic **Banking Interface**. The goal is to apply Object-Oriented Programming (OOP) concepts to manage a customer's bank account, allowing them to interact with the system through a menu-driven interface.

Problem Statement

Modern banking requires efficient and secure ways to handle customer transactions. You are tasked with creating a **Customer Management Module** for "STATE BANK OF INDIA" that performs the following tasks:

1. **Account Initialization:** When a user starts the application, they should be greeted and prompted to enter their name to initialize a new account with a default balance of ₹1000.
2. **Deposit Functionality:** Users should be able to add money to their account. The system must update the total balance and display the new amount immediately.
3. **Withdrawal Functionality:** Users should be able to withdraw money, provided they have sufficient funds.

   Constraint: If a user attempts to withdraw more than their current balance, the system should display an "Insufficient Funds" error and terminate the session for security.
4. **Continuous Interaction:** The application must run in a loop, allowing the user to perform multiple transactions (Deposit or Withdraw) until they choose to exit.
5. **Input Validation:** The system should handle invalid menu choices by notifying the user to select a valid option.

Key Technical Requirements

- **OOP Concepts:** Use a `Customer` class with an `__init__` constructor and instance methods for `deposit` and `withdraw`.
- **Static Attributes:** Use a class-level variable to store the bank's name.
- **Control Flow:** Implement a `while True` loop with `if-elif-else` conditions to handle the menu logic.
- **Error Handling:** Use the `sys.exit()` function to gracefully (or forcefully) close the program when required.
